

Data Structures and Algorithms for Engineers

Module 3: Searching and Sorting Algorithms

Lecture 1: Linear and binary search. In-place sorts: bubblesort, selection sort, insertion sort.

Linear (Sequential) Search

Linear (Sequential) Search

- Begin at the beginning of the list
- Proceed through the list, sequentially and element by element,
- Until the **key** is encountered
or
Until the end of the list is reached

Linear (Sequential) Search

- Note: we treat a list as a **general concept, decoupled from its implementation**
- The order of complexity is $O(n)$
- The list does not have to be in sorted order

Implementation of linear search in C

```
int linear_search(item_type s[], item_type key, int low, int high) {  
  
    int i;  
  
    i = low;  
  
    while ((s[i] != key) && (i < high)) {  
        i = i+1;  
    }  
  
    if (s[i] == key) {  
        return (i);  
    }  
    else {  
        return(-1);  
    }  
}
```

Binary Search

- If the list is sorted, we can use a more efficient $O(\log_2(n))$ search strategy
- Check to see whether the **key** is
 - equal to
 - less than
 - greater than

the middle element

Binary Search

- If key is **equal** to the middle element, then **terminate** (found)
- If key is **less than** the middle element, then search the **left half**
- If key is **greater than** the middle element, then search the **right half**
- Continue until either
 - the key is found or
 - there are no more elements to search

Implementation of Binary_Search

Pseudo-code

```
binary_search(list, key, lower_bound, upper_bound)
```

identify sublist to be searched by setting bounds on search

REPEAT

 get middle element of list

 if middle element < key

 then reset bounds to make the **right** sublist
 the list to be searched

 else reset bounds to make the **left** sublist
 the list to be searched

UNTIL list is empty or key is found

Implementation of binary search in C (iterative approach)

```
typedef char item_type;

int binary_search(item_type s[], item_type key, int low, int high) {

    int first, last, mid;

    first = low;
    last  = high;

    do {
        mid = (first + last) / 2;
        if (s[mid] < key) {
            first = mid + 1;
        }
        else {
            last = mid - 1;
        }
    } while ( (first <= last) && (s[mid] != key) );

    if (s[mid] == key)
        return (mid);
    else
        return (-1);
}
```

Binary Search

```
first:  
last:  
mid:  
list[mid]:  
key: P
```

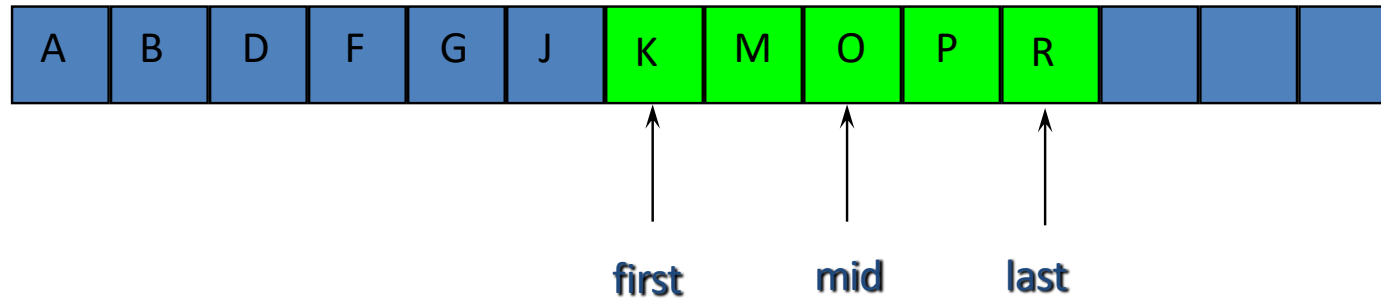

Should really have written these as 'P', 'A', 'B', ... because they are character values

Binary Search

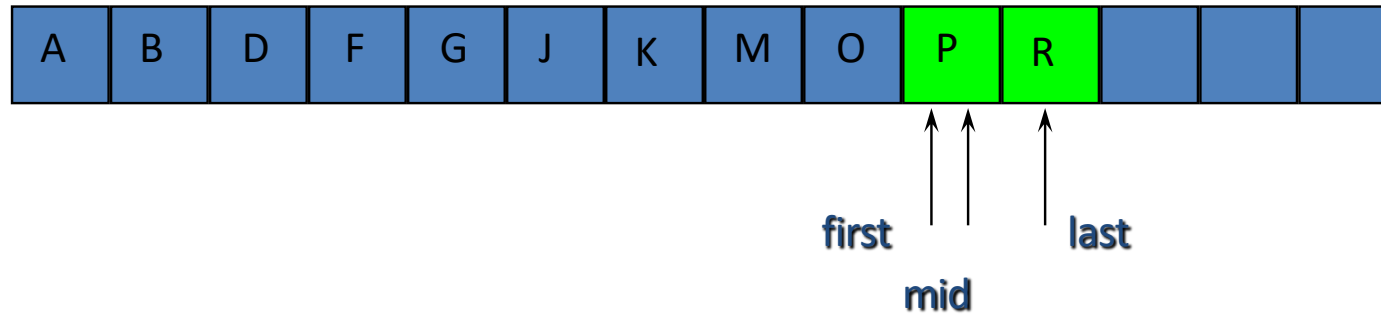

```
first:    1
last:    11
mid:      6
list[mid]: J
key:      P
```

Binary Search

```
first:    1    7
last:    11   11
mid:      6    9
list[mid]: J   O
key:      P    P
```

Binary Search

| | | | |
|------------|----|----|----|
| first: | 1 | 7 | 10 |
| last: | 11 | 11 | 11 |
| mid: | 6 | 9 | 10 |
| list[mid]: | J | O | P |
| key: | P | P | P |

← FOUND!

Binary Search

```
first:  
last:  
mid:  
list[mid]:  
key:      E
```

Binary Search

```
first:    1
last:    11
mid:      6
list[mid]: J
key:      E
```

Binary Search

```
first:    1    1
last:     11   5
mid:      6    3
list[mid]: J   D
key:      E    E
```

Binary Search

```
first:    1    1    4
last:     11   5    5
mid:      6    3    4
list[mid]: J    D    F
key:     E    E    E
```

Binary Search

| | | | | | |
|------------|----|---|---|---|----------------------------|
| first: | 1 | 1 | 4 | 4 | ← first > last: NOT FOUND! |
| last: | 11 | 5 | 5 | 3 | |
| mid: | 6 | 3 | 4 | 3 | |
| list[mid]: | J | D | F | D | |
| key: | E | E | E | E | |

Implementation of binary search in C (recursive approach)

```
typedef char item_type;

int binary_search(item_type s[], item_type key, int low, int high) {

    int mid;

    if (low > high) return (-1); /* key not found */

    mid = (low + high) / 2;

    if (s[mid] == key) return(mid);

    if (s[mid] > key) {
        return(binary_search(s, key, low, mid-1));
    }
    else {
        return(binary_search(s, key, mid+1, high));
    }
}
```

Sorting Algorithms

The Sorting Problem

Input: A sequence of n numbers $\langle a_1, a_2, \dots, a_n \rangle$

Output: the permutation (reordering) of the input sequence such that
 $a_1 \leq a_2 \leq \dots \leq a_n$

Sorting Algorithms

- In-place sorts
 - Small number of elements stored outside the input data structure
 - Additional space requirements $O(1)$
 - Tradeoff: more computationally-complex algorithms (slower sorts)
 - Bubble Sort
 - Selection Sort
 - Insertion Sort

Sorting Algorithms

- Not-in-place sort
 - Additional space requirements not $O(1)$
 - Tradeoff: less computationally-complex algorithms but greater memory requirements (possibly unpredictable)
 - Quick Sort
 - Merge Sort
- Characteristics of a good sort

Bubble Sort

- Assume we are sorting a list represented by an array A of n integer elements
- Bubble sort algorithm in pseudo-code

```
FOR every element in the list,  
    proceeding from the first to the last
```

```
    WHILE list element > previous list element  
        bubble element back (up) the list  
        by successive swapping with  
        the element just above/prior it
```

Bubble Sort

| | | | | |
|----|---|---|----|---|
| 10 | 9 | 8 | 11 | 4 |
|----|---|---|----|---|

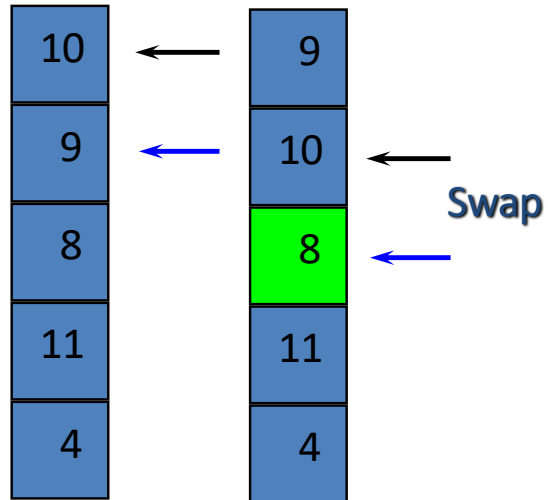

Bubble Sort

Bubble Sort

Bubble Sort

Bubble Sort

Bubble Sort

Bubble Sort

Implementation of Bubble_Sort()

```
int bubble_sort(int *a, int size) { // int a[]
    int i,j, temp;

    for (i=0; i < size-1; i++) { // why?
        for (j=i; j >= 0; j--) { // Because initially j=i
            if (a[j] > a[j+1]) { // and we access element j+1

                /* swap */
                temp = a[j+1];
                a[j+1] = a[j];
                a[j] = temp;
            }
        }
    }
}
```

Note that this is an inefficient naive implementation. It doesn't use the while condition in the pseudo-code:

```
WHILE list element > previous list element
```

It uses a for loop and blindly compares all elements right back to the beginning of the list, swapping when necessary.

Exercise: reimplement this more efficiently with the while loop.

Bubble Sort

A few observations:

- we don't usually sort numbers; we usually sort records with keys
 - the key can be a number
 - or the key could be a string
 - the record would be represented with a **struct**
- The swap should be done with a function (so that a record can be swapped)
- We can make the preceding algorithm more efficient. How?
(hint: do we always have to bubble back to the top?)

Bubble Sort

Exercise: implement these changes and write a driver program to test:

- the original bubble sort
- the more efficient bubble sort
- the bubble sort with a swap function
- the bubble sort with structures
- compute the order of time complexity of the bubble sort

Selection Sort

Example:

- Shaded elements are selected
- Boldface elements are in order

Initial Array

| | | | | |
|----|----|----|-----------|----|
| 29 | 10 | 14 | 37 | 13 |
|----|----|----|-----------|----|

After 1st swap

| | | | | |
|-----------|----|----|----|-----------|
| 29 | 10 | 14 | 13 | 37 |
|-----------|----|----|----|-----------|

After 2nd swap

| | | | | |
|----|----|-----------|-----------|-----------|
| 13 | 10 | 14 | 29 | 37 |
|----|----|-----------|-----------|-----------|

After 3rd swap

| | | | | |
|-----------|----|-----------|-----------|-----------|
| 13 | 10 | 14 | 29 | 37 |
|-----------|----|-----------|-----------|-----------|

After 4th swap

| | | | | |
|-----------|-----------|-----------|-----------|-----------|
| 10 | 13 | 14 | 29 | 37 |
|-----------|-----------|-----------|-----------|-----------|

Selection Sort

- Assume we are sorting a list represented by an array A of n integer elements
- Selection sort algorithm in pseudo-code

```
last = n-1
Do
    Select largest element from a[0..last]
    Swap it with a[last]
    last = last-1
While (last >= 1)
```

Selection Sort

```
typedef int DataType;

void selectionSort(DataType a[], int n) {

    DataType temp;
    int index_of_largest, index, last;

    for(last= n-1; last >= 1; last--) {

        // select largest item in a[0..last]
        index_of_largest = 0;
        for(index=1; index <= last; index++) {
            if (a[index] > a[index_of_largest])
                index_of_largest = index;
        }

        // swap largest item with last element
        temp = a[index_of_largest];
        a[index_of_largest] = a[last];
        a[last] = temp;
    }
}
```

Insertion Sort

```
typedef int DataType;

insertion_sort(DataType a[], int n) {

    int i,j;
    int temp;

    for (i=1; i<n; i++) {
        j=i;
        while ((j>0) && (a[j] < a[j-1])) {
            temp = a[j-1]; // swap
            a[j-1] = a[j];
            a[j] = temp;

            j = j-1;
        }
    }
}
```
