# Finding the Shortest Path in a Map

## Environment map

- If we represent the map as a graph
  - Free cells are **vertices** in one or more **connected components**
  - Obstacle cells are vertices in one or more connected components
    - Not strictly necessary because the robot path is confined to the free space connected component(s)
- We can use **graph traversal algorithms** to find the shortest path connecting a start position and a goal position

# Finding the Shortest Path in a Map

## Environment map

Vertices represent free space, i.e. navigable space

What about the edges? There are two possibilities

1. A vertex can be connected to four horizontal neighbour vertices: 4-connectivity
  - All edges represent the same distance, e.g. 1

Use an unweighted graph

# Finding the Shortest Path in a Map

## Environment map

2. A vertex can be connected to all eight neighbour vertices: **8-connectivity**

- Horizontal edges represent distance of 1
- Diagonal edges represent a distance of  $\sqrt{2}$

Need to use a **weighted graph**:

- weight of 1 for horizontal and vertical edges
- weight  $\sqrt{2}$  of for diagonal edges

# Finding the Shortest Path in a Map

## Environment map

2. A vertex can be connected to all eight neighbour vertices: **8-connectivity**

- Horizontal edges represent distance of 1
- Diagonal edges represent a distance of  $\sqrt{2}$

Need to use a **weighted graph**:

- weight of 1 for horizontal and vertical edges
- weight  $\sqrt{2}$  of for diagonal edges

# Dijkstra's Shortest Path Algorithm

- Finds shortest path between **start and destination** vertices

Some implementations find the shortest path between a start vertex and all other vertices, i.e. **shortest path spanning tree rooted in the start vertex**

- $O(n^2)$  with simple data structures

# Dijkstra's Shortest Path Algorithm

- Greedy algorithm
- Repeatedly select the **smallest weight edge** that will extend the path
  - Begin with some start vertex,
  - Extend the path, one edge at a time
  - Until all vertices are included
- Thus, incrementally construct the shortest path to all vertices

# Dijkstra's Shortest Path Algorithm

The principle behind Dijkstra's algorithm is that

if  $(s, \dots, x, \dots, t)$  is the shortest path from  $s$  to  $t$ ,  
then  $(s, \dots, x)$  had better be the shortest path from  $s$  to  $x$ .

This suggests a dynamic programming-like strategy:

We store the distance from  $s$  to all **nearby vertices**,  
and use them to find the shortest path to **more distant vertices**.

# Dijkstra's Shortest Path Algorithm

```
known = {s}  
for i = 1 to n, dist[i] = ∞  
for each edge (s, v), dist[v] = d(s, v)  
last=s  
while (last ≠ t)  
    select v such that dist(v) = minunknown dist(i)  
    for each (v, x), dist[x] = min(dist[x], dist[v] + w(v, x))  
    last=v  
    known = known ∪ {v}
```

Select from the unknown vertices

# Dijkstra's Shortest Path Algorithm

ShortestPath-Dijkstra( $G, s, t$ )

path = { $s$ }

for  $i = 1$  to  $n$ ,  $\text{dist}[i] = \infty$

for each edge  $(s, v)$ ,  $\text{dist}[v] = w(s, v)$  // **initial** distances are just the weights

last =  $s$

while (last  $\neq$   $t$ )

    select  $v_{\text{next}}$ , the unknown vertex **minimizing**  $\text{dist}[v]$

**for each edge**  $(v_{\text{next}}, x)$

        if  $\text{dist}[x] > \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{dist}[x] = \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{parent}[x] = v_{\text{next}}$

last =  $v_{\text{next}}$

path = path  $\cup$  { $v_{\text{next}}$ }

# Dijkstra's Shortest Path Algorithm

ShortestPath-Dijkstra( $G, s, t$ )

path = { $s$ }

for  $i = 1$  to  $n$ ,  $\text{dist}[i] = \infty$

for each edge  $(s, v)$ ,  $\text{dist}[v] = w(s, v)$  // **initial** distances are just the weights

last =  $s$

while (last  $\neq$   $t$ )

    select  $v_{\text{next}}$ , the unknown vertex **minimizing  $\text{dist}[v]$**

**for each edge  $(v_{\text{next}}, x)$**

        if  $\text{dist}[x] > \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{dist}[x] = \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{parent}[x] = v_{\text{next}}$

last =  $v_{\text{next}}$

path = path  $\cup$  { $v_{\text{next}}$ }

The weight of edge  $(s, v)$  from vertex  $s$  to vertex  $v$

# Dijkstra's Shortest Path Algorithm

ShortestPath-Dijkstra( $G, s, t$ )

path = { $s$ }

for  $i = 1$  to  $n$ ,  $\text{dist}[i] = \infty$

for each edge  $(s, v)$ ,  $\text{dist}[v] = w(s, v)$  // **initial** distances are just the weights

last =  $s$

while (last  $\neq$   $t$ )

select  $v_{\text{next}}$ , the unknown vertex **minimizing  $\text{dist}[v]$**

**for each edge  $(v_{\text{next}}, x)$**   We now have a new way of reaching  $x$  ...

if  $\text{dist}[x] > \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$  

$\text{dist}[x] = \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$  

parent $[x] = v_{\text{next}}$  

last =  $v_{\text{next}}$

path = path  $\cup$  { $v_{\text{next}}$ }

if the total distance to  $x$  is less than the current distance

update the total distance to  $x$

Record the parent of  $x$

# Dijkstra's Shortest Path Algorithm

ShortestPath-Dijkstra( $G, s, t$ )

path = { $s$ }

for  $i = 1$  to  $n$ ,  $\text{dist}[i] = \infty$

for each edge  $(s, v)$ ,  $\text{dist}[v] = w(s, v)$  // **initial** distances are just the weights

last =  $s$

while (last  $\neq$   $t$ )

select  $v_{\text{next}}$ , the unknown vertex **minimizing  $\text{dist}[v]$**

**for each edge  $(v_{\text{next}}, x)$**

if  $\text{dist}[x] > \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{dist}[x] = \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

parent $[x] = v_{\text{next}}$

last =  $v_{\text{next}}$

path = path  $\cup$  { $v_{\text{next}}$ }

Extend the path from the vertex  
with the shortest distance so far

# Dijkstra's Shortest Path Algorithm

ShortestPath-Dijkstra( $G, s, t$ )

path = { $s$ }

for  $i = 1$  to  $n$ ,  $\text{dist}[i] = \infty$

for each edge  $(s, v)$ ,  $\text{dist}[v] = w(s, v)$  // **initial** distances are just the weights

last =  $s$

while (last  $\neq$   $t$ )

select  $v_{\text{next}}$ , the unknown vertex **minimizing  $\text{dist}[v]$**

**for each edge  $(v_{\text{next}}, x)$**

if  $\text{dist}[x] > \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

$\text{dist}[x] = \text{dist}[v_{\text{next}}] + w(v_{\text{next}}, x)$

parent $[x] = v_{\text{next}}$

last =  $v_{\text{next}}$

path = path  $\cup$  { $v_{\text{next}}$ }

This can be implemented efficiently using a priority queue  
(implemented as a binary heap)

# Dijkstra's Shortest Path Algorithm

```
/* Dijkstra's algorithm */

dijkstra(graph *g, int start) {
    int i;                /* counter */
    edgenode *p;         /* temporary pointer */
    bool intree[MAXV+1]; /* is the vertex in the tree yet? */
    int distance[MAXV+1]; /* cost of adding to tree */
    int parent[MAXV+1];  /* parent vertex */
    int v;               /* current vertex to process */
    int w;               /* candidate next vertex */
    int weight;          /* edge weight */
    int dist;            /* best current distance from start */

    for (i=1; i<=g->nvertices; i++) {
        intree[i] = FALSE;
        distance[i] = MAXINT;
        parent[i] = -1;
    }

    distance[start] = 0;
    v = start;
```

S. Skiena, The Algorithm Design Manual, Springer 2010

# Dijkstra's Shortest Path Algorithm

```
while (intree[v] == FALSE) {
    intree[v] = TRUE;
    p = g->edges[v];
    while (p != NULL) {
        w = p->y;
        weight = p->weight;
        if ((distance[v] + weight < distance[w])) { // can we improve
            distance[w] = distance[v] + weight; // on the distance to w?
            parent[w] = v;
        }
        p = p->next;
    }
    v = 1;
    dist = MAXINT;
    for (i=1; i<=g->nvertices; i++)
        if ((intree[i] == FALSE) && (distance[i] < dist)) {
            dist = distance[i];
            v = i;
        }
    }
}
```

S. Skiena, The Algorithm Design Manual, Springer 2010

# Dijkstra's Shortest Path Algorithm

"Illustration of Dijkstra's algorithm finding a path from a start node (lower left, red) to a goal node (upper right, green) in a robot motion planning problem. Open nodes represent the "tentative" set (aka set of "unvisited" nodes). Filled nodes are visited ones, with color representing the distance: the greener, the closer. Nodes in all the different directions are explored uniformly, appearing more-or-less as a circular wavefront as Dijkstra's algorithm uses a heuristic identically equal to 0."

[https://en.wikipedia.org/wiki/Dijkstra%27s\\_algorithm](https://en.wikipedia.org/wiki/Dijkstra%27s_algorithm)

# Shortest Paths

## Dijkstra's Algorithm

- This implementation finds the shortest path spanning tree, i.e. shortest path between a `start` vertex and all other vertices
- The length of the shortest path from `start` to a given vertex `t` is exactly the value of `distance[t]`
- To find the actual path, follow the `parent` relations from `t` until we hit `start` (or -1 if no such path exists)
- We did this in Breadth-First Search

```
find_path(int start, int end, int parents[])
```
